

## ***Characterizing Vertical Air Pollution Gradients in the Urban Environment***

---

Marloes Eeftens, Postdoctoral Researcher, [marloes.eeftens@unibas.ch](mailto:marloes.eeftens@unibas.ch)

## A few measurement sites can serve to obtain high resolution concentration maps and exposure estimates

But: if 2 people have the same pixel value on this map: do you have the same residential exposures?

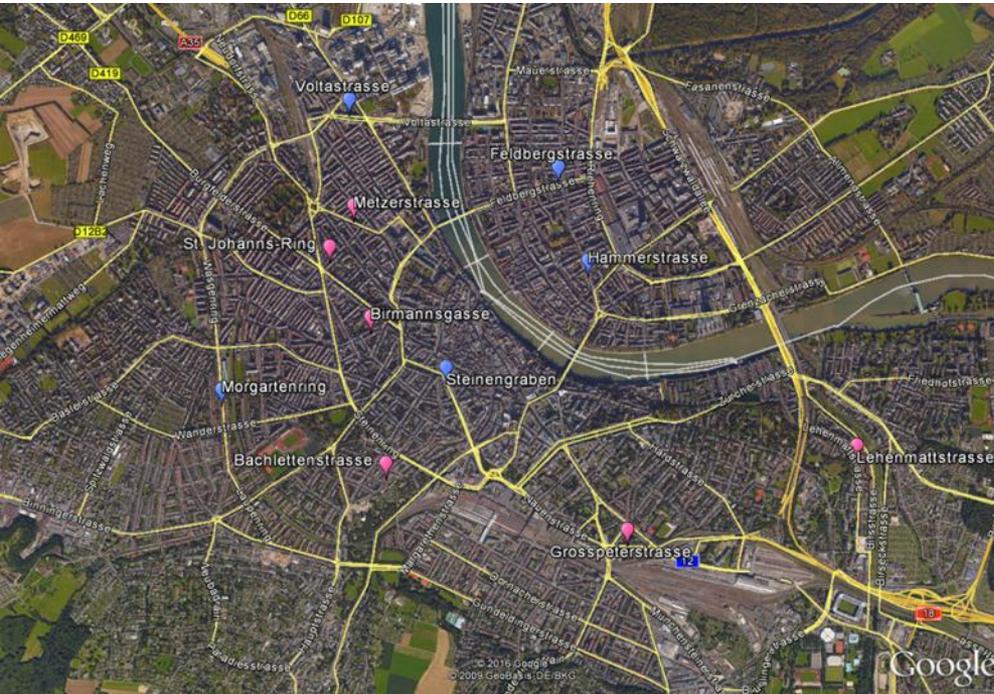

**Research question:  
Are people living at higher floors differently exposed to air  
pollution (& noise)?**

## Study design:

- 11 Streets with different traffic intensity and street configuration in Basel Stadt
- Pollutants:
  - Ultrafine particle count
  - Black carbon
  - Noise
  - Particle size distribution
  - PM2.5
- 30 minute real-time sample
- 2 seasons (summer / winter)
- Up to 6 different heights: (1.5, 4, 7, 11, 17 and 25m)

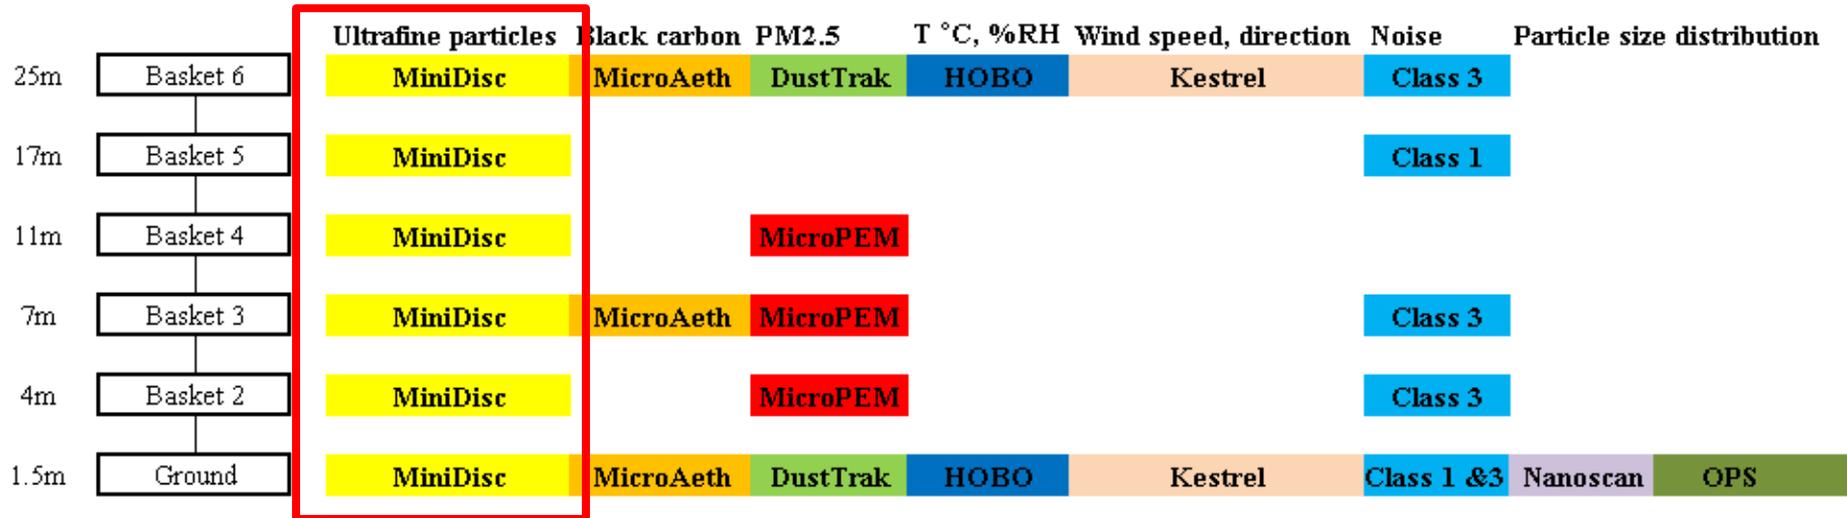

# Setup of baskets and sampling heights

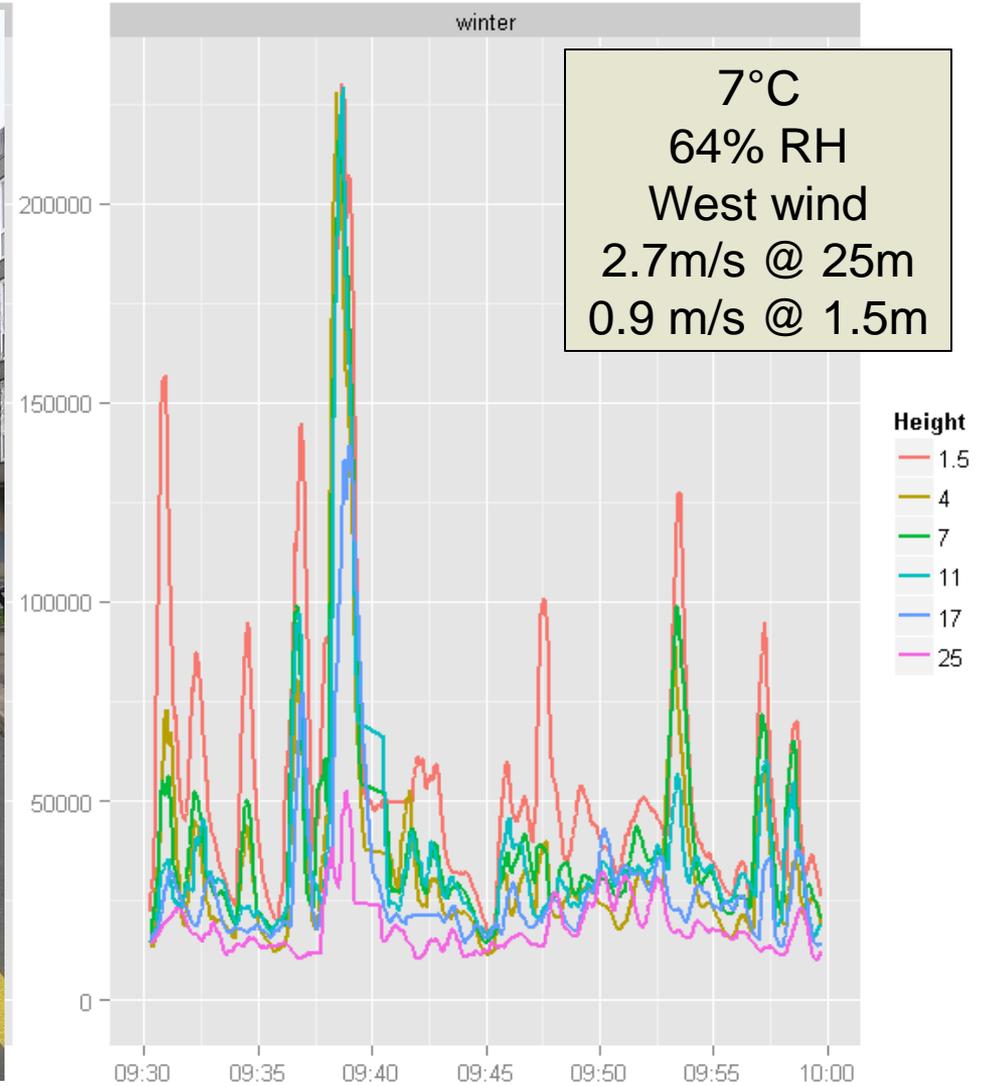

- Miniature Diffusion Size Classifier (MiniDiSC) (Fachhochschule Nordwestschweiz, Switzerland) (Fierz et al., 2011)
- Particles in the size range of 10 to 300 nm
- Flow rate of 1.0 l/min.
- Raw data were collected at 1 second logging intervals

# Grosspeterstrasse, Basel

- 896 cars + 52 trucks during 30 minutes
- 19m wide, rooflines 23m tall

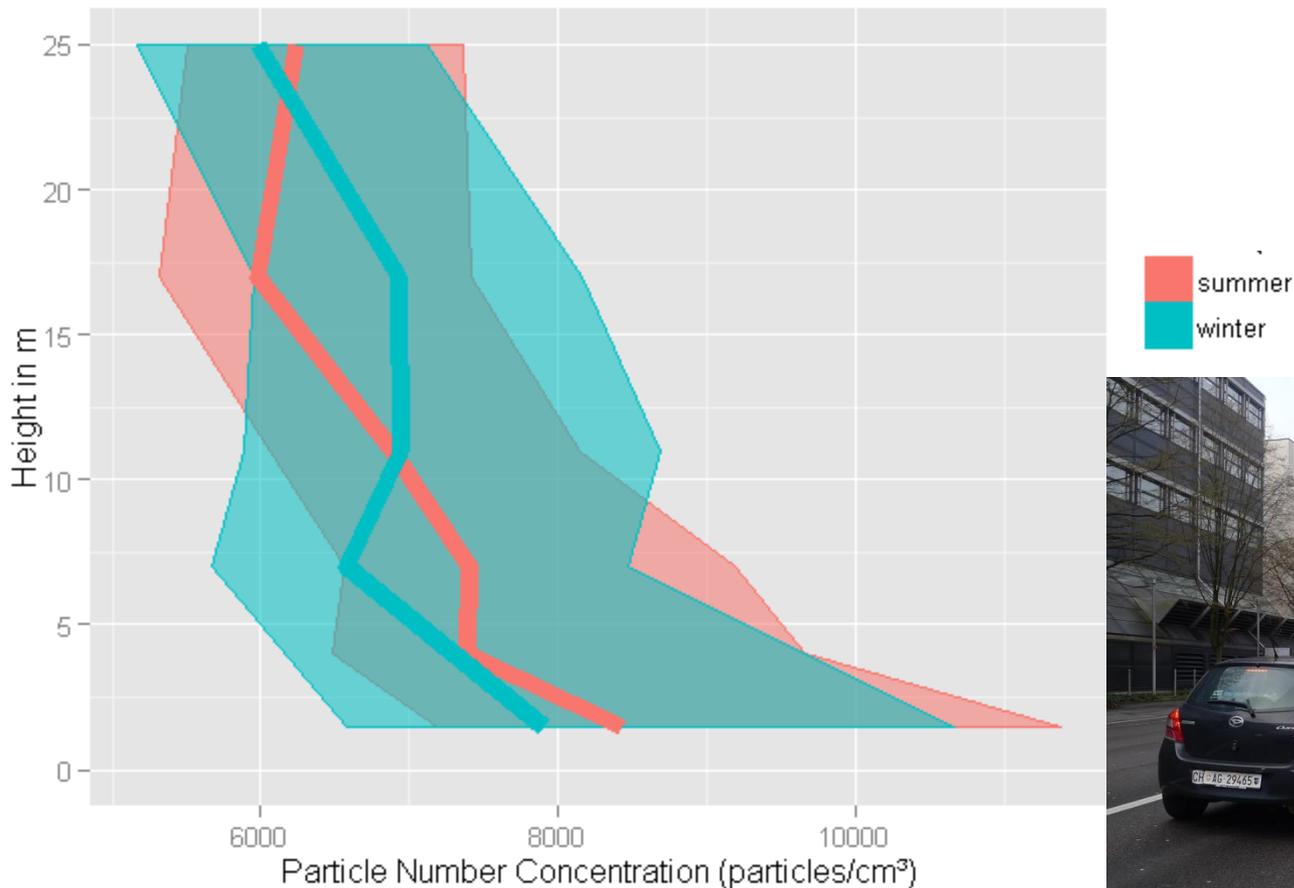

# The pattern is similar at all sites:

- Peaks occur mainly at the lower heights
- Lowest concentrations generally occur at 25m

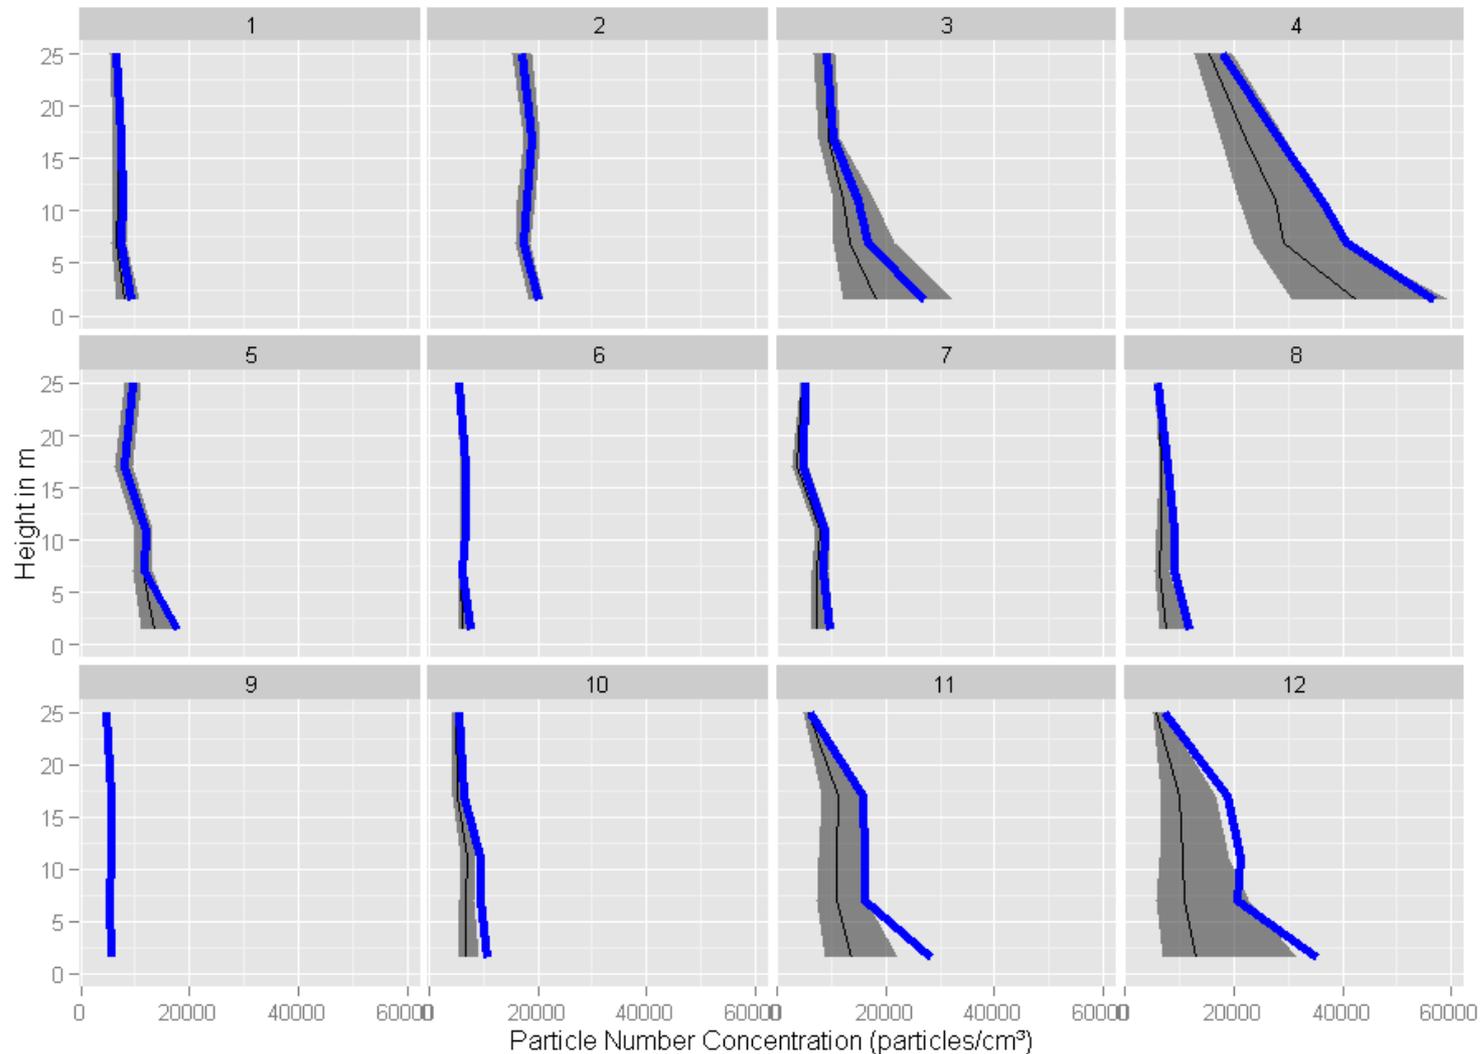

# There is a non-linear decrease with height in Particle Number Concentration in both summer and winter.

Median concentration and interquartile range by height (m)

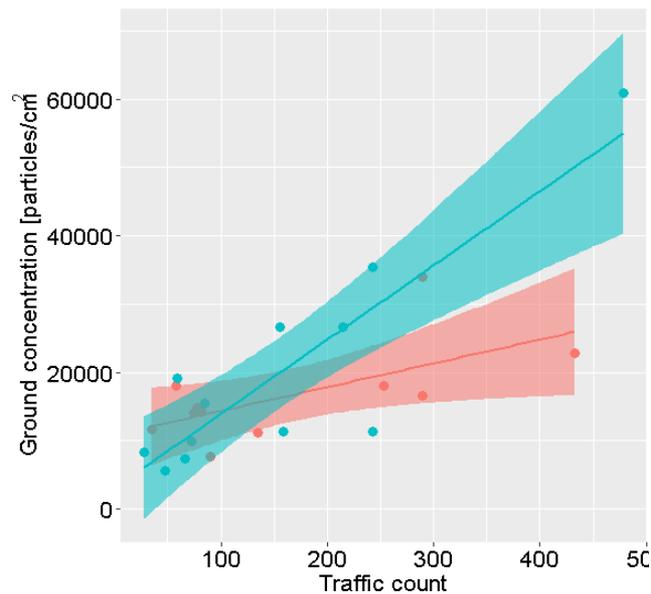

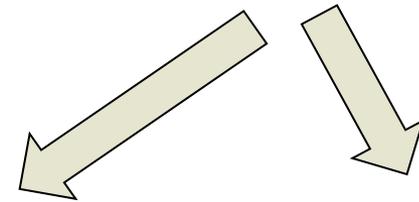

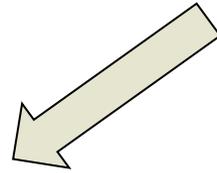

**There is a steeper decrease in very busy streets**  
**The mean decreases steeper than the median, because of peaks**

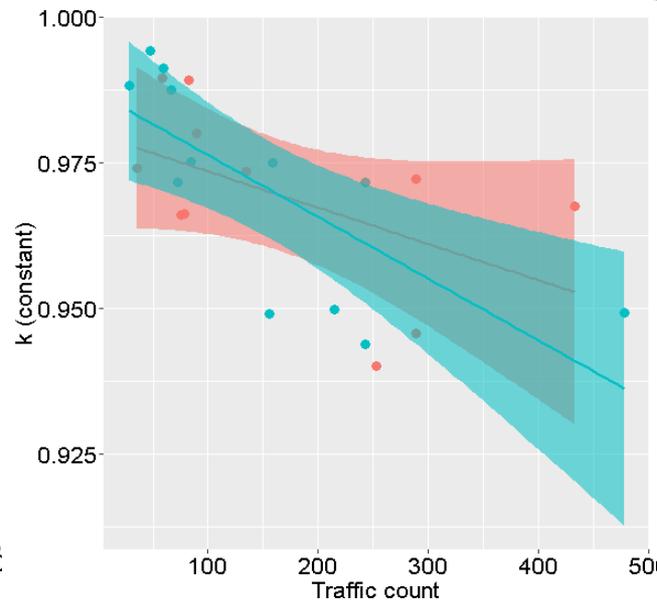

We can describe the relation between height and concentration:

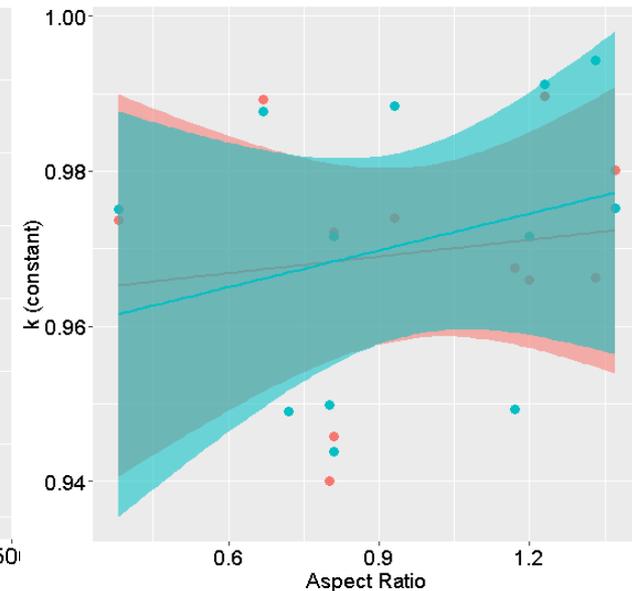

$$Concentration_h = Concentration_{ground} \times e^{-k h}$$

More traffic →  
higher ground concentration

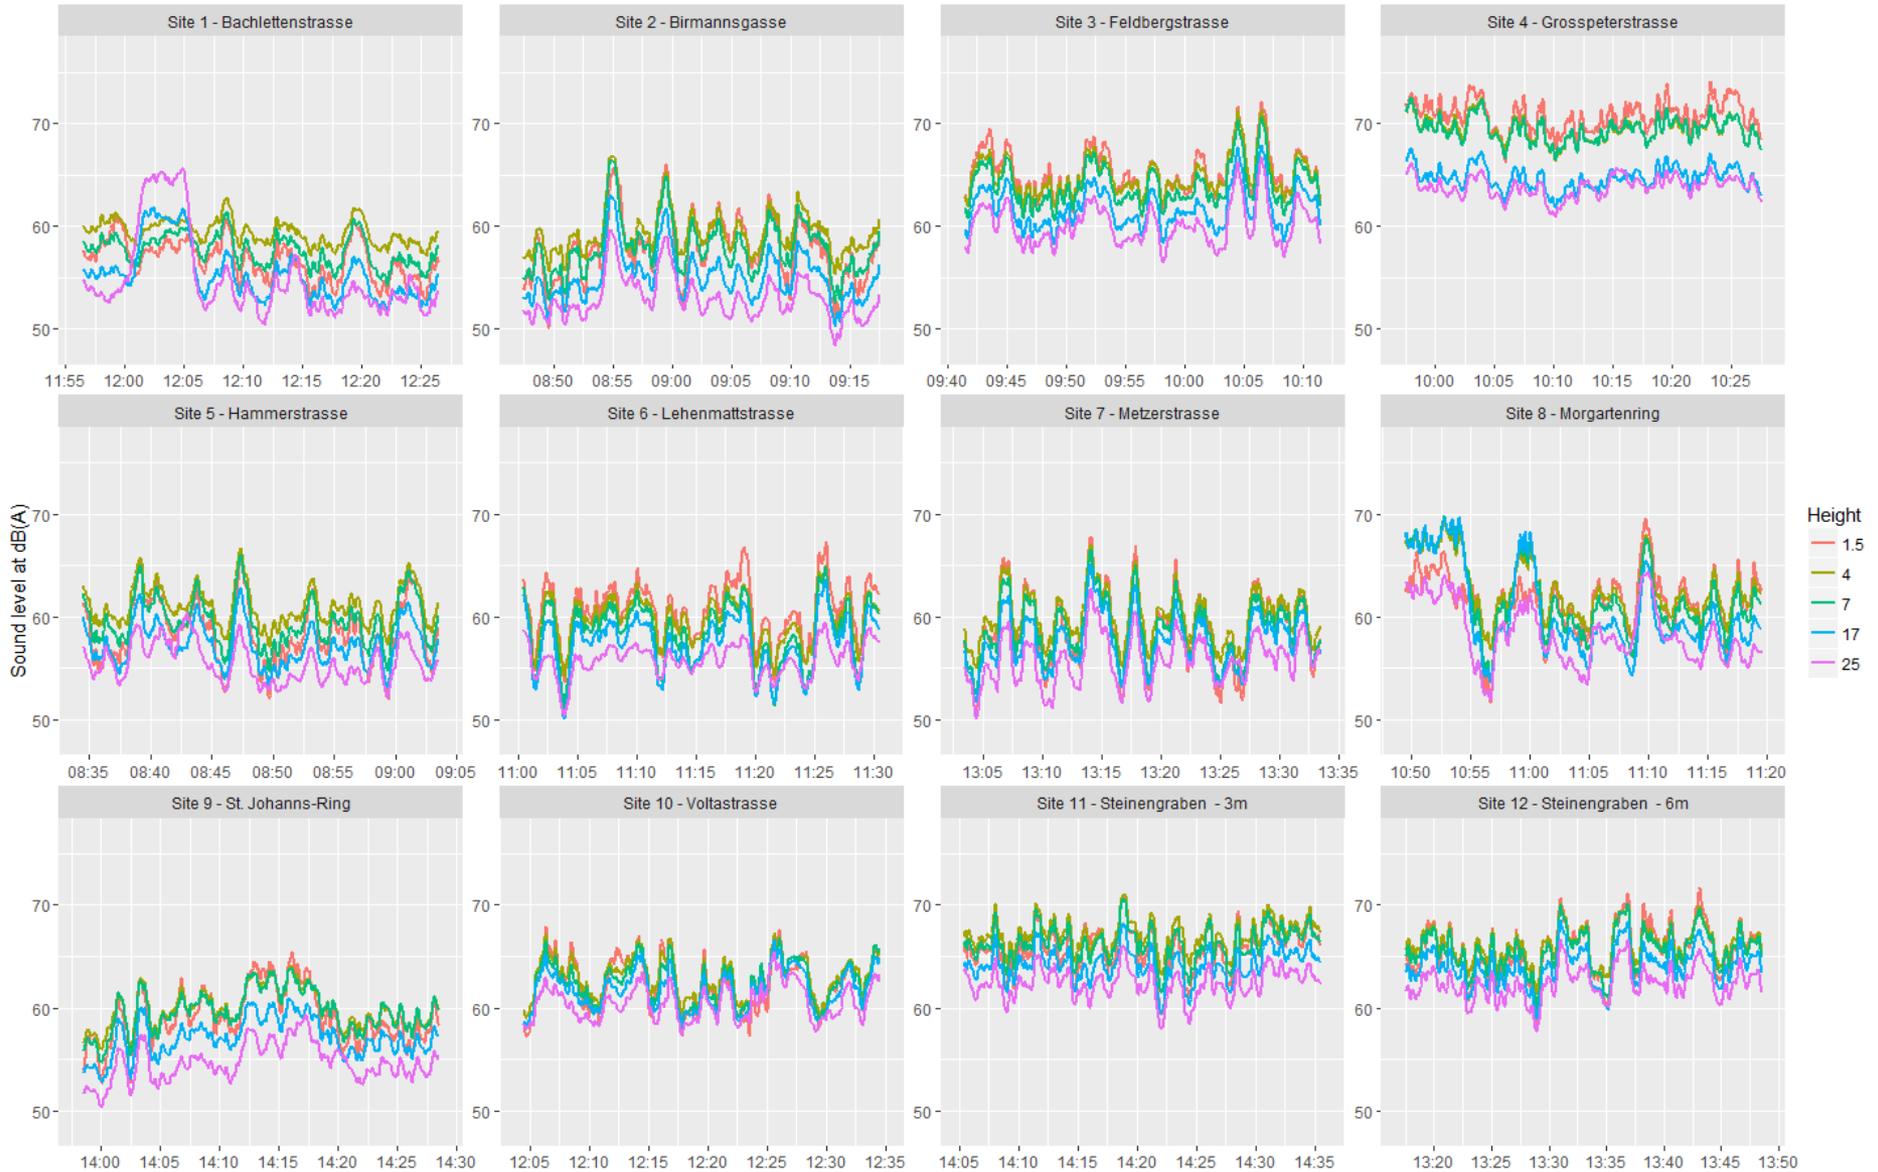

More traffic →  
More decay with height (k)

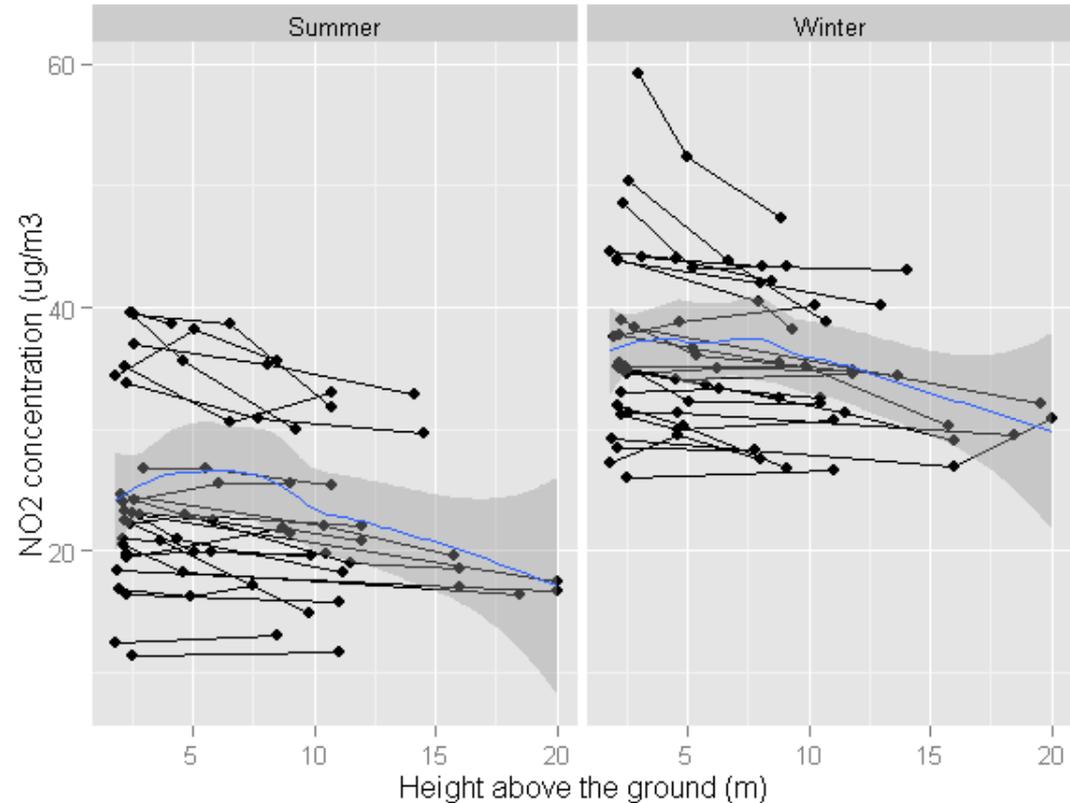

Higher Aspect Ratio →  
Less decay with height (k)

# We see a similar pattern for noise

# Vertical gradients matter on the long term also!

- Two-week  $\text{NO}_2$  measurements at 26 places in Basel, summer and winter
- $\text{NO}_2$  Concentration decreases with increasing height (non-linear)
- $\text{NO}_2$  decreases more with height if the concentration was high at ground level

drivers of Maltech AG

### Conclusions:

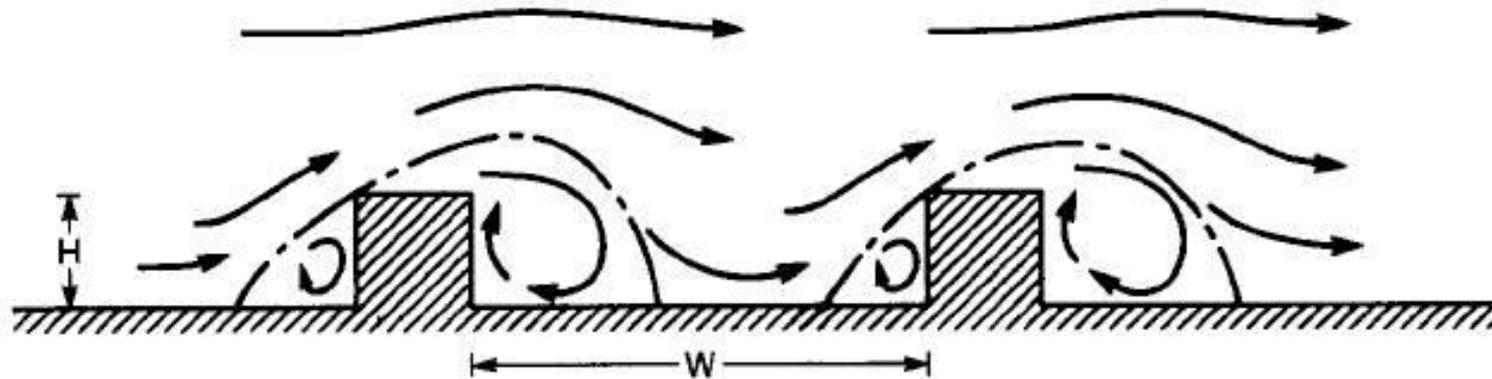

- There is room for improvement in air pollution exposure characterization, especially in cities with a lot of high-rise.
- Exposure is especially overestimated for people living at height along busy streets.
- Digital data on building height and floor of residence is increasingly available. Let's use it!
