

# Specific BET Surface Area Measurement of Low-Mass-Samples

E. Karg, G. A. Ferron, G. Schumann and O. Schmid

Institute for Inhalation Biology, Helmholtz Center Munich, D-85758 Neuherberg/Munich, Germany

Keywords: Aerosol sampling, black carbon, particle characterization, measurement errors, BET specific surface area of particles.

## Introduction

The specific surface area (SSA) of carbonaceous particles has shown better correlation with biological effects than other parameters such as particle diameter or organic content (Oberdörster et al., 2005; Stoeger et al., 2006; Stoeger et al., 2007). However, especially for particles with low SSA, relatively large amounts of sample (here: up to 100 mg) are needed for reliable BET surface area measurements. In this study we present an analysis of systematic errors in SSA due to low sample mass and describe how to define the lower detection limit of the instrument and how to correct for these errors.

## Method

Up to seven samples with different mass from four types of carbonaceous particles were analyzed with an automated BET sorptometer (Porous materials Inc., USA) with nitrogen as test gas molecules. All data were taken at isothermal conditions at the boiling point of nitrogen (77 K). Sample preparation included surface cleaning by thermal desorption during a 2 hr period at 20  $\mu$ Torr (vacuum) and 250 °C.

The measured SSA ( $SSA_m$ ) data were fitted according to

$$SSA_m = \frac{A_d + A_p}{M_p} = \frac{A_d}{M_p} + SSA_o \quad (1)$$

where  $A_d$  is assumed to be a virtual internal surface area of the instrument,  $A_p$  is the particle surface area of the sample,  $M_p$  is the sample mass and  $SSA_o$  is the true SSA of the particles.

## Results and Discussion

For each material, the parameters  $A_d$  and  $SSA_o$  were determined by fitting equation (1) to the data sets (Figure 1).

All fits showed regression coefficients better than 0.89 and  $p < 0.02$ . The fit parameters  $SSA_o$  agree with  $SSA_s$  (given by the suppliers) within 22 % (see Table 1).

For a better estimate of  $A_d$ , all  $SSA_m$  values were normalized with the material's  $SSA_o$  and plotted against the particles' surface area  $A_p = M_p SSA_o$  (Figure 2). This transformation allows to incorporate all data into one single fit yielding a more reliable  $A_d$  of 0.33 m<sup>2</sup>. As indicated there, the data provide correct SSA values (bias = 1) only for sufficiently large surface areas (or sample mass).

For the BET instrument used here, a standard deviation of 7.5 % was found for samples of sufficient high mass. Therefore, two different regimes of bias can be distinguished: a bias  $> 7.5$  % in SSA for samples with  $A_p$  smaller than about 5 m<sup>2</sup> and  $< 7.5$  % for  $A_p > 5$  m<sup>2</sup>.

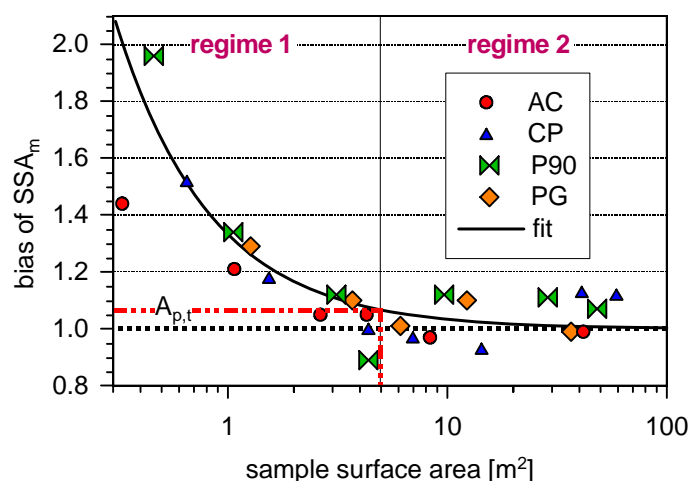

We hypothesize that  $A_d$  is evoked by blank and dead space corrections which are inadequate in accuracy for the low-mass problem.

## Conclusions

The method presented here can be used to determine the lower threshold area  $A_{p,t}$  (and the corresponding mass) to achieve results within the instrument's standard deviation. It additionally can be used to correct for biases in the measured  $SSA_m$  values assuming a virtual internal instrument surface area. Biases however are particularly pronounced for low-mass samples.

# Definition of SSA

$$SSA = A / M$$

$M = \text{const}$

# SSA is sensitive to structure

- additionally to form factor, the SSA is sensitive to the material's structure
- the texture is taken into account
- techniques are well developed

<http://www.wasser-wissen.de/abwasserlexikon/a/aktivkohle.htm>

# Measurement techniques

- Microscopic
- Chemical absorption of molecules
- Attachment of ions
- Physical adsorption of molecules

**EMSA** (Electron microscope surface area)

**Iodine absorption, CTAB**

(Cetyltrimethylammonium Bromide, withdrawn by the American Society for Testing and Materials (ASTM) in 2007)

**ASA** (active surface area Rogak et al., 1991)

$$ASA_m = \frac{d_{SMD}^2}{\rho d_{MMD}^3}$$

Attachment of ions to particles < 100 nm is proportional to the surface area of the particles (Pandis, JAS 22(4), p.417, 1991)

**Condensation methods:**

Volumetric, radiometric, gas chromatographic vacuum-microbalance, piezo-gravimetric, Millikan-oil-drop

# Measurement principle

## Methods are not new:

- Irving Langmuir received the Nobel prize 1932 for fundamental work in surface chemistry
- Stephen Brunauer, P.H. Emmet and Edward Teller (BET) developed their theory of interpretation of adsorption isothermes
- Adsorption Isotherme:  
 $T = 77\text{K}$  (boiling point of  $\text{N}_2$ )  
 $0 < P/P_0 < 1$

e.g.  $\text{N}_2$  molecule  $d_M \sim 0.1\text{nm}$   
 $S_M \sim 16A^2 \sim 0.16\text{nm}^2$

$$S = N_{\text{ads}} S_M$$

# BET equation

## The BET equation

$$\frac{P}{v(P_o - P)} = \frac{1}{v_m c} + \frac{c-1}{v_m c} \frac{P}{P_o}$$

$$c = \exp\left(\frac{E_1 - E_L}{RT}\right)$$

- v: adsorbed volume
- v<sub>m</sub>: volume of the mono layer
- c: BET constant
- E<sub>1</sub>: Heat of adsorption Layer1
- E<sub>L</sub>: Heat of ads. Layer2 ... n

# Measurement setup

## Volumetric method:

- Outgassing (remove H<sub>2</sub>O, CO<sub>2</sub>)
- Cool with liquid N<sub>2</sub> (constant level)
- Fill calibrated volume
- Release into sample volume
- Adsorbed volume: calculate from pressure difference

### Advantages:

- Mostly glass surfaces
- Direct measurement
- Various gases (N<sub>2</sub>, Ar, Kr, Xe)
- Robust (vibration, electrostatics, ...)
- Outgassing in the same containment
- Commercially available

### Disadvantages:

- Blank correction necessary
- Dead space correction necessary
- Adherent particles above N<sub>2liq</sub>

# The lower the mass ...

## Aerosol science samples ... ... meet material science methods

- Material science: enough sample mass available ( $\gg 100$  mg)
- Aerosol science: sample mass is very very limited ( $\ll 10$  mg)

50 µg / 1.3 kg ~ 40 ppb

1 g of sample ~ 800 tons of air

1 mg of sample ~ 800 kg of air (1000 m³)

Lab: 1 mg of sample ~ 8 kg of air (10m³)

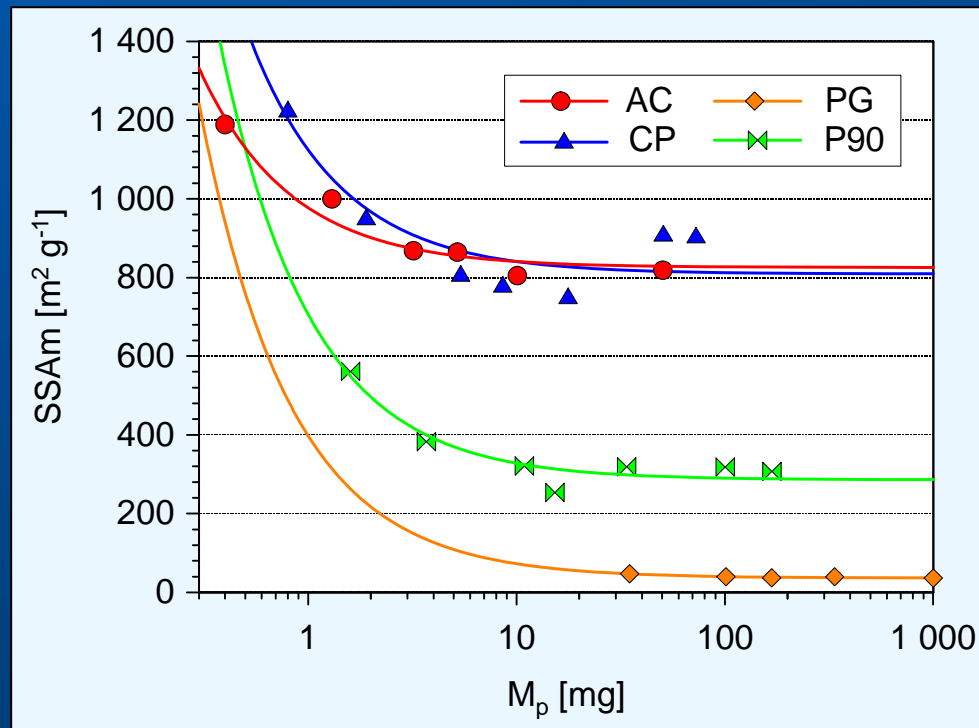

# Performed experiments

- 4 carbonaceous substances of different surface area
- Produce several (~7) aliquots of each substance
- Measure all of them under optimal repeatability conditions (instrument, vial, operator, ...)

## Substances:

AC:	activated charcoal ( $d_o = \text{n.a.}$ , SSA ~ 900 m <sup>2</sup> /g)
P90	Degussa Printex 90 ( $d_o = 14$ nm, SSA ~ 300 m <sup>2</sup> /g)
PG	Degussa Printex G ( $d_o = 50$ nm, SSA ~ 30 m <sup>2</sup> /g)
CP	Palas electric spark soot ( $d_o = 5-10?$ nm, SSA = ?)

# Overview of all data sets

- wide variation of SSA
- All data sets show a bias for low mass samples

# Fit equations

$$SSA_m = \frac{A_d + A_p}{M_p} = \frac{A_d}{M_p} + SSA_o$$

equ (1)

$$\frac{SSA_m}{SSA_o} = \frac{A_d}{A_p} + 1$$

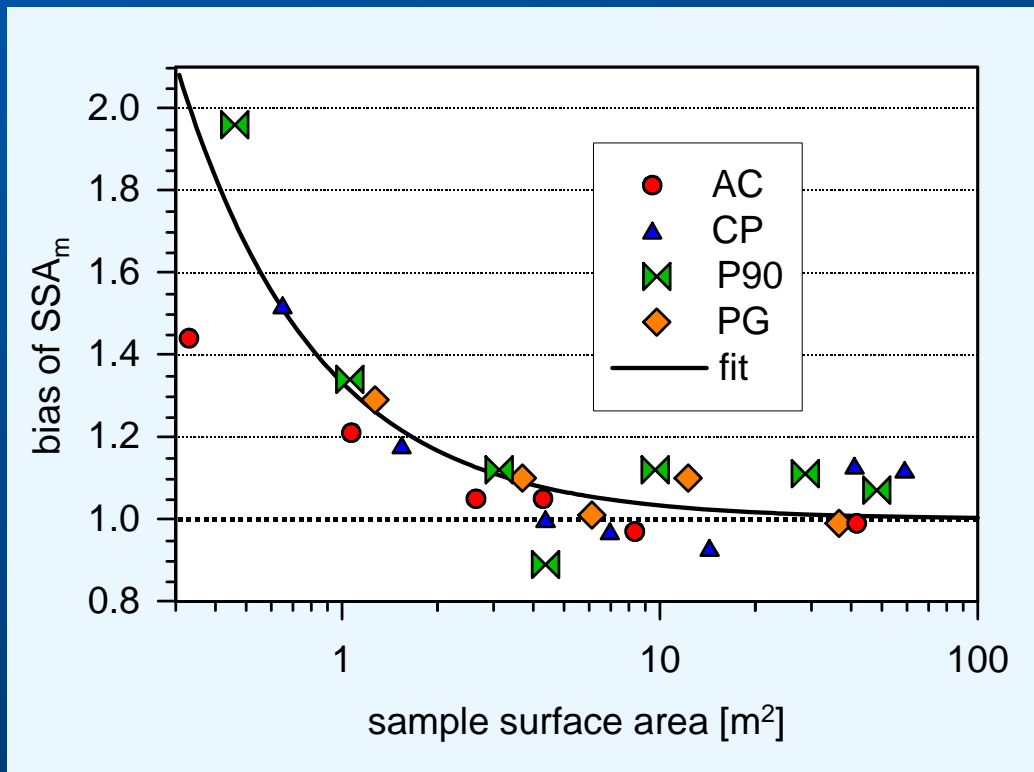

equ (2)

$SSA_m$	measured SSA
$A_d$	unaccounted apparent surface area
$A_p$	surface area of particles
$M_p$	mass of particulates
$SSA_o$	true specific surface area of the particles

- All corrections are applied
- Working hypothesis: unaccounted apparent surface area NOT from particle sample
- Normalization shows the relation to be **SUBSTANCE independent**
- limiting cases:  
 $A_d \rightarrow 0$   
 $A_p \rightarrow 0$

# And applies it to the data sets

	AC	CP	P90	PG
$SSA_s$ [ $m^2/g$ ]	1000	n.a.	300	30
$SSA_o$ [ $m^2/g$ ]	826	809	286	36.5
$A_d$ [ $m^2$ ]	0.152	0.316	0.421	0.362
R	0.98	0.89	0.95	0.93
$M_{p,min}$ [mg]	4.0	4.1	11.5	90

Fit the equation to  
ALL data sets

$$A_d = 0.267$$

$$R = 0.80$$

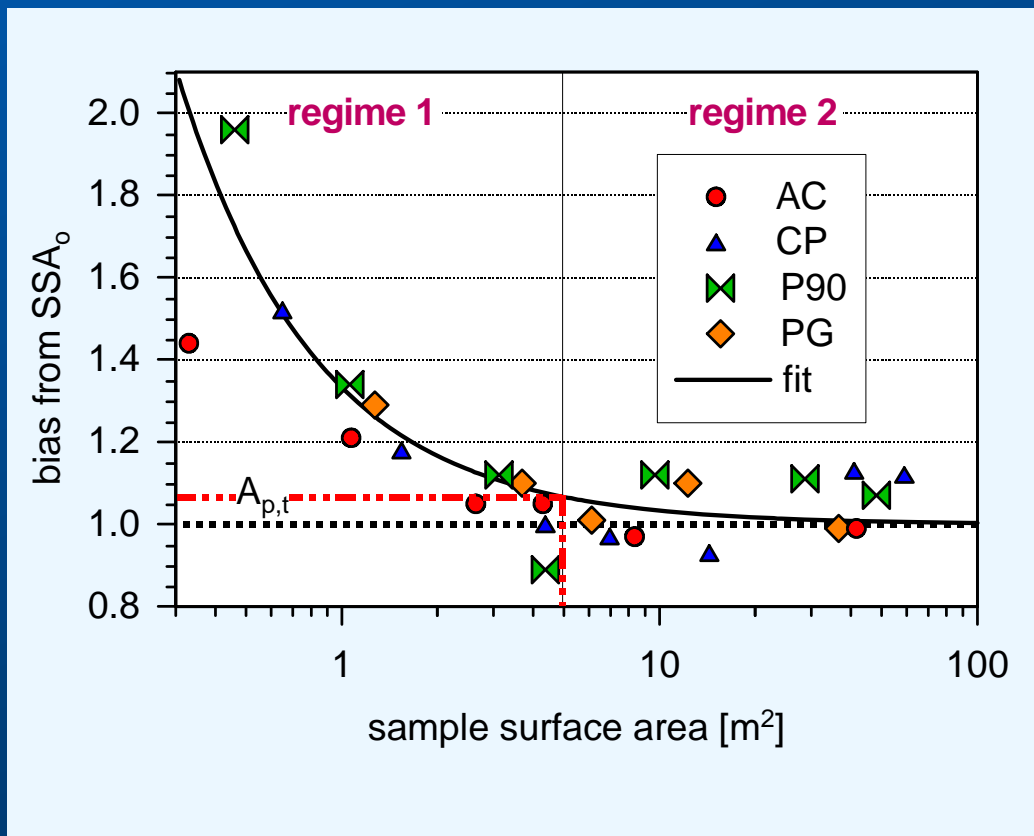

# Findings

- Low sample mass bias is consistent with an unaccounted instrument surface area
- $A_d$  is  $\sim$  constant within measurement error  $\rightarrow$  cannot explained by impurities in the sampling vial

## Possible explanations:

- limited accuracy of blank?
- dead space correction?
- temperature stability?

# The mass threshold

- Define 2 regimes by fit line:
- 7.5% is the instrument's s.d.
- Threshold (7.5%) ist  $5m^2$

# Conclusions

- Each instrument has to be calibrated for low sample mass (determine  $A_d$ ) by an additional calibration step
  - Determine  $A_d$  for low sample mass
  - Repeat Calibration if new blank correction is applied
- A threshold surface area of 5 m<sup>2</sup> is found for our instrument

# Take home message

- The BET-SSA is expected to become more important because it correlates well with biological endpoints
- However: corrections for low-sample-mass artifacts have to be applied!

# Thank you for your attention
